

# Lecture 4

Torgeir R. Hvidsten  
Assistant professor in Bioinformatics  
Umeå Plant Science Center (UPSC)  
Computational Life Science Centre (CLiC)

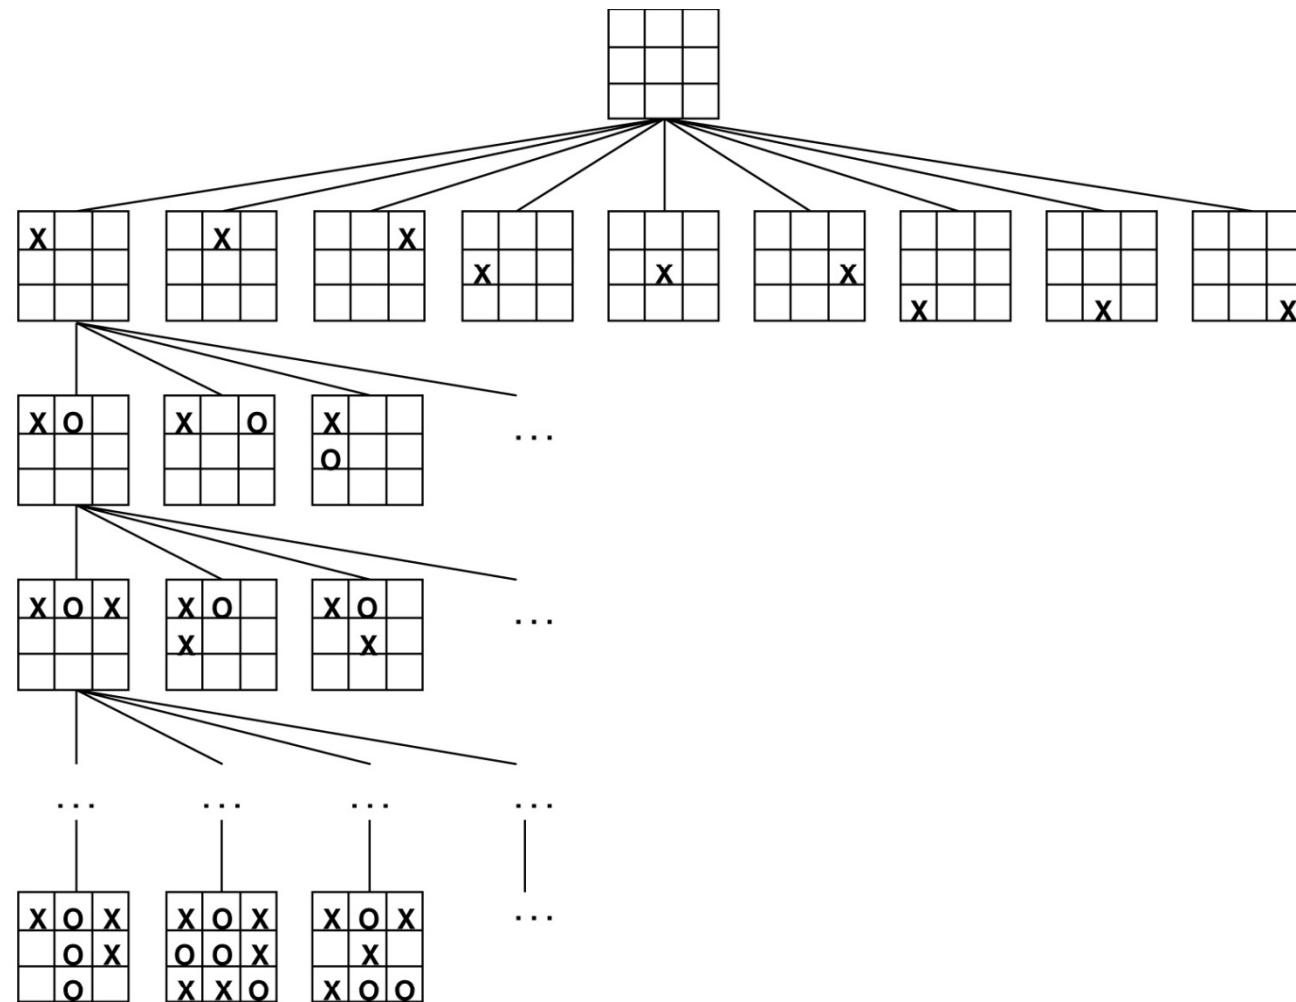

# This lecture

- Go through Lab 3
- Correct versus incorrect algorithms
- Time/space complexity analysis
- Basic algorithm design: exhaustive search, greedy algorithms, dynamic programming and randomized algorithms

# Algorithm

- Algorithm: a sequence of instructions that one must perform in order to solve a well-formulated problem
- **Correct algorithm:** translate every input instance into the correct output
- Incorrect algorithm: there is at least one input instance for which the algorithm does not produce the correct output
- Many successful algorithms in bioinformatics are not “correct”

# Search space

# Algorithm design (I)

- Exhaustive algorithms (brute force): examine every possible alternative to find the solution
- Branch-and-bound algorithms: omit searching through a large number of alternatives by branch-and-bound or pruning
- Greedy algorithms: find the solution by always choosing the currently "best" alternative
- Dynamic programming: use the solution of the subproblems of the original problem to construct the solution

# Algorithm design (II)

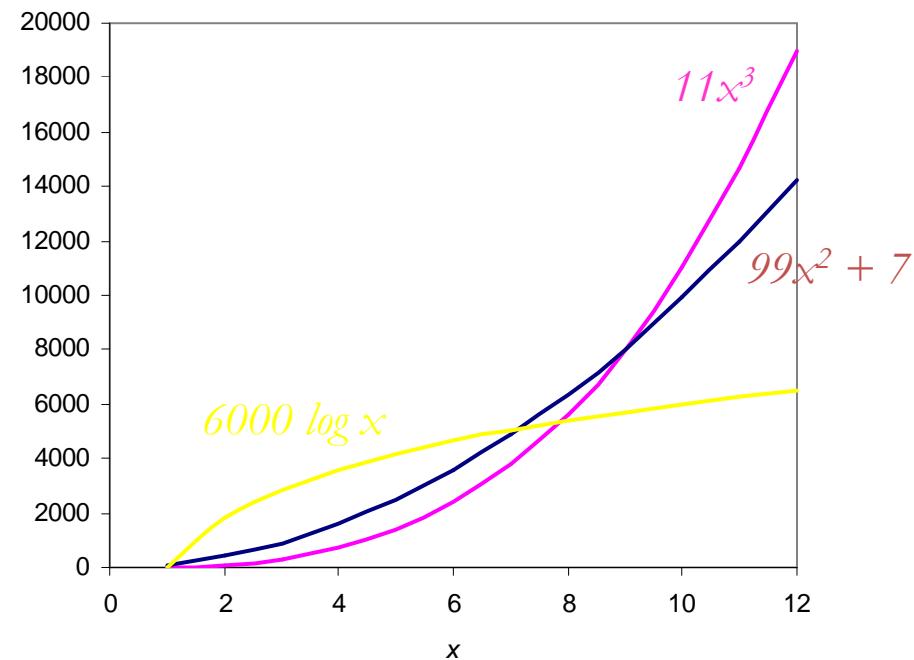

- Divide-and-conquer algorithms: splits the problem into subproblems and solve the problems independently
- Machine learning: induce models based on previously labeled observations (examples)
- Randomized algorithms: finds the solution based on randomized choices

# Algorithm complexity

- The **Big-O notation**:
  - the running time of an algorithm as a function of the size of its input
  - worst case estimate
  - asymptotic behavior
- $O(n^2)$  means that the running time of the algorithm on an input of size  $n$  is limited by the quadratic function of  $n$

# Big-O Notation

A function  $f(x)$  is  $O(g(x))$  if there are positive real constants  $c$  and  $x_0$  such that  $f(x) \leq cg(x)$  for all values of  $x \geq x_0$ .

# Sorting algorithm

Sorting problem: Sort a list of  $n$  integers  $\mathbf{a} = (a_1, a_2, \dots, a_n)$

SelectionSort( $\mathbf{a}, n$ )

- 1     **for**  $i \leftarrow 1$  **to**  $n-1$
- 2          $j \leftarrow$  Index of the smallest element  
                among  $a_i, a_{i+1}, \dots, a_n$
- 3         Swap elements  $a_i$  and  $a_j$
- 4     **return**  $\mathbf{a}$

# Example run

$i = 1:$  (7,92,87,**1**,4,3,2,6)

$i = 2:$  (**1**,**92**,87,7,4,3,**2**,6)

$i = 3:$  (1,**2**,**87**,7,4,**3**,92,6)

$i = 4:$  (1,**2**,**3**,**7**,**4**,87,92,6)

$i = 5:$  (1,**2**,**3**,**4**,**7**,87,92,**6**)

$i = 6:$  (1,**2**,**3**,**4**,**6**,**87**,92,**7**)

$i = 7:$  (1,**2**,**3**,**4**,**6**,**7**,**92**,**87**)

(1,2,3,4,6,7,87,92)

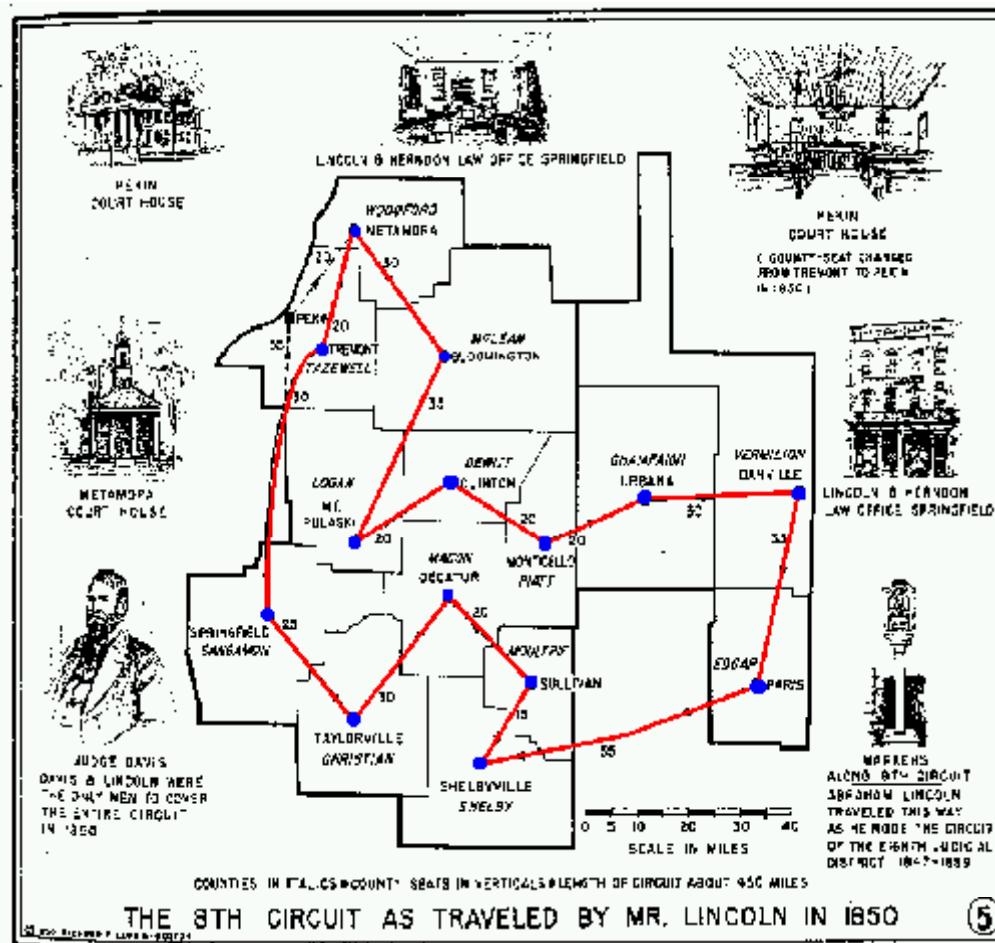

# Complexity of SelectionSort

- Makes  $n - 1$  iterations in the for loop
- Analyzes  $n - i + 1$  elements  $a_i, a_{i+1}, \dots, a_n$  in iteration  $i$
- Approximate number of operations:
  - $n + (n-1) + (n-2) + \dots + 2 + 1 = n(n+1)/2$
- Thus the algorithm is  $O(n^2)$

# Tractable versus intractable problems

- Some problems requires polynomial time
  - e.g. sorting a list of integers
  - called **tractable** problems
- Some problems require exponential time
  - e.g. listing every subset in a list
  - called **intractable** problems
- Some problems lie in between
  - e.g. the traveling salesman problem
  - called **NP-complete** problems
  - nobody have proved whether a polynomial time algorithm exists for these problems

# Traveling salesman problem

Exhaustive search:  
Finding regulatory motifs in  
DNA sequences

# Random sample

# Parameters

# Motifs: Profiles and consensus

Alignment	a G g t a c T t C c A t a c g t a c g t T A g t a c g t C c A t C c g t a c g G
Profile	A 3 0 1 0 3 1 1 0 C 2 4 0 0 1 4 0 0 G 0 1 4 0 0 0 3 1 T 0 0 0 5 1 0 1 4
Consensus	A C G T A C G T

Score 3+4+4+5+3+4+3+4=30

- Line up the patterns by their start indexes

$$\mathbf{s} = (s_1, s_2, \dots, s_t)$$

- Construct a profile with frequencies of each nucleotide in columns
- Consensus nucleotide in each position has the highest score in column

# BruteForceMotifSearch

BruteForceMotifSearch( $\textbf{DNA}$ ,  $t$ ,  $n$ ,  $l$ )

```
1   bestScore  $\leftarrow 0$ 
2   for each  $\mathbf{s} = (s_1, s_2, \dots, s_t)$  from  $(1, 1, \dots, 1)$  to  $(n-l+1, \dots, n-l+1)$ 
3     if ( $\text{Score}(\mathbf{s}, \textbf{DNA}) > \text{bestScore}$ )
4       bestScore  $\leftarrow \text{Score}(\mathbf{s}, \textbf{DNA})$ 
5       bestMotif  $\leftarrow (s_1, s_2, \dots, s_t)$ 
6   return bestMotif
```

# Running Time of BruteForceMotifSearch

- Varying  $(n - l + 1)$  positions in each of  $t$  sequences, we're looking at  $(n - l + 1)^t$  sets of starting positions
- For each set of starting positions, the scoring function makes  $l$  operations, so complexity is
$$l(n - l + 1)^t = O(ln^t)$$
- That means that for  $t = 8$ ,  $n = 1000$ , and  $l = 10$  we must perform approximately  $10^{20}$  computations – it will take billions of years!

# The median string problem

- Given a set of  $t$  DNA sequences, find a pattern that appears in all  $t$  sequences with the minimum number of mutations
- This pattern will be the motif

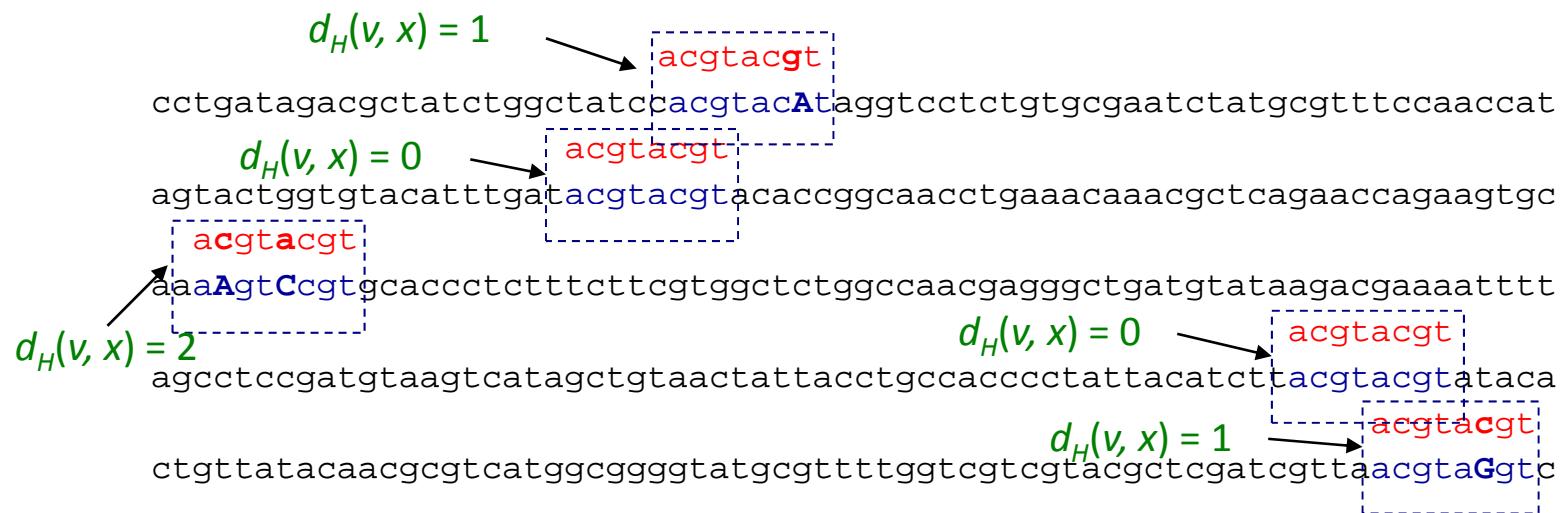

# Hamming Distance

- Hamming distance:
  - $d_H(v, w)$  is the number of nucleotide pairs that do not match when  $v$  and  $w$  are aligned. For example:

$$d_H(\text{AAAAAA}, \text{ACAAAAC}) = 2$$

# Total Distance: Example

- Given  $v = \text{“acgtacgt”}$

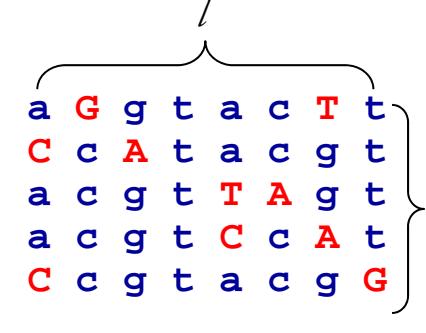

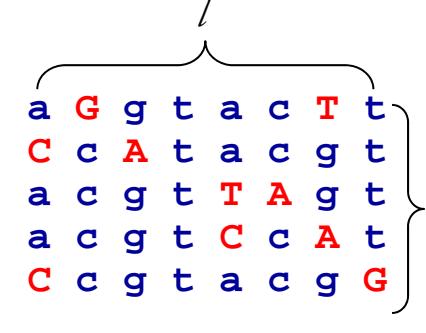

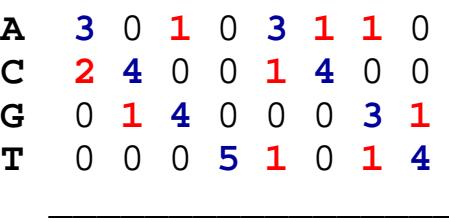

- $\text{TotalDistance}(v, \text{DNA}) = 1+0+2+0+1 = 4$

# Median string search algorithm

BruteForceMedianStringSearch ( $\textbf{DNA}$ ,  $t$ ,  $n$ ,  $l$ )

- 1      $bestWord \leftarrow \text{AAA...A}$
- 2      $bestDistance \leftarrow \infty$
- 3     **for** each  $l$ -mer  $v$  **from** AAA...A to TTT...T
- 4         **if**  $TotalDistance(v, \textbf{DNA}) < bestDistance$
- 5              $bestDistance \leftarrow TotalDistance(v, \textbf{DNA})$
- 6              $bestWord \leftarrow v$
- 7     **return**  $bestWord$

# Motif finding problem = median string problem

		
Alignment		<ul style="list-style-type: none"> <li>• At any column <math>i</math>  <math>\text{Score}_i + \text{TotalDistance}_i = t</math></li> </ul>
Profile		<ul style="list-style-type: none"> <li>• Because there are <math>l</math> columns  <math>\text{Score} + \text{TotalDistance} = l \times t</math></li> </ul>
Consensus		<ul style="list-style-type: none"> <li>• Rearranging:  <math>\text{Score} = l \times t - \text{TotalDistance}</math></li> </ul>
<b>Score</b>	$3+4+4+5+3+4+3+4$	
<b>TotalDistance</b>	$2+1+1+0+2+1+2+1$	
Sum	$5 \ 5 \ 5 \ 5 \ 5 \ 5 \ 5 \ 5$	<ul style="list-style-type: none"> <li>• <math>l \times t</math> is constant, thus the minimization of TotalDistance is equivalent to the maximization of Score</li> </ul>

## Motif finding problem vs. median string problem

Why bother reformulating the *motif finding* problem into the *median string* problem?

- The motif finding problem needs to examine all the combinations for  $s$ . That is  $(n - l + 1)^t$  combinations
- The median string problem needs only to examine all  $4^l$  combinations for  $v$ .

Greedy search:  
Finding regulatory motifs in  
DNA sequences

# Approximation algorithms

- These algorithms find **approximate solutions** rather than **optimal solutions**
- The **approximation ratio** of an algorithm A on input  $\pi$  is:

$$A(\boldsymbol{\pi}) / \text{OPT}(\boldsymbol{\pi})$$

where

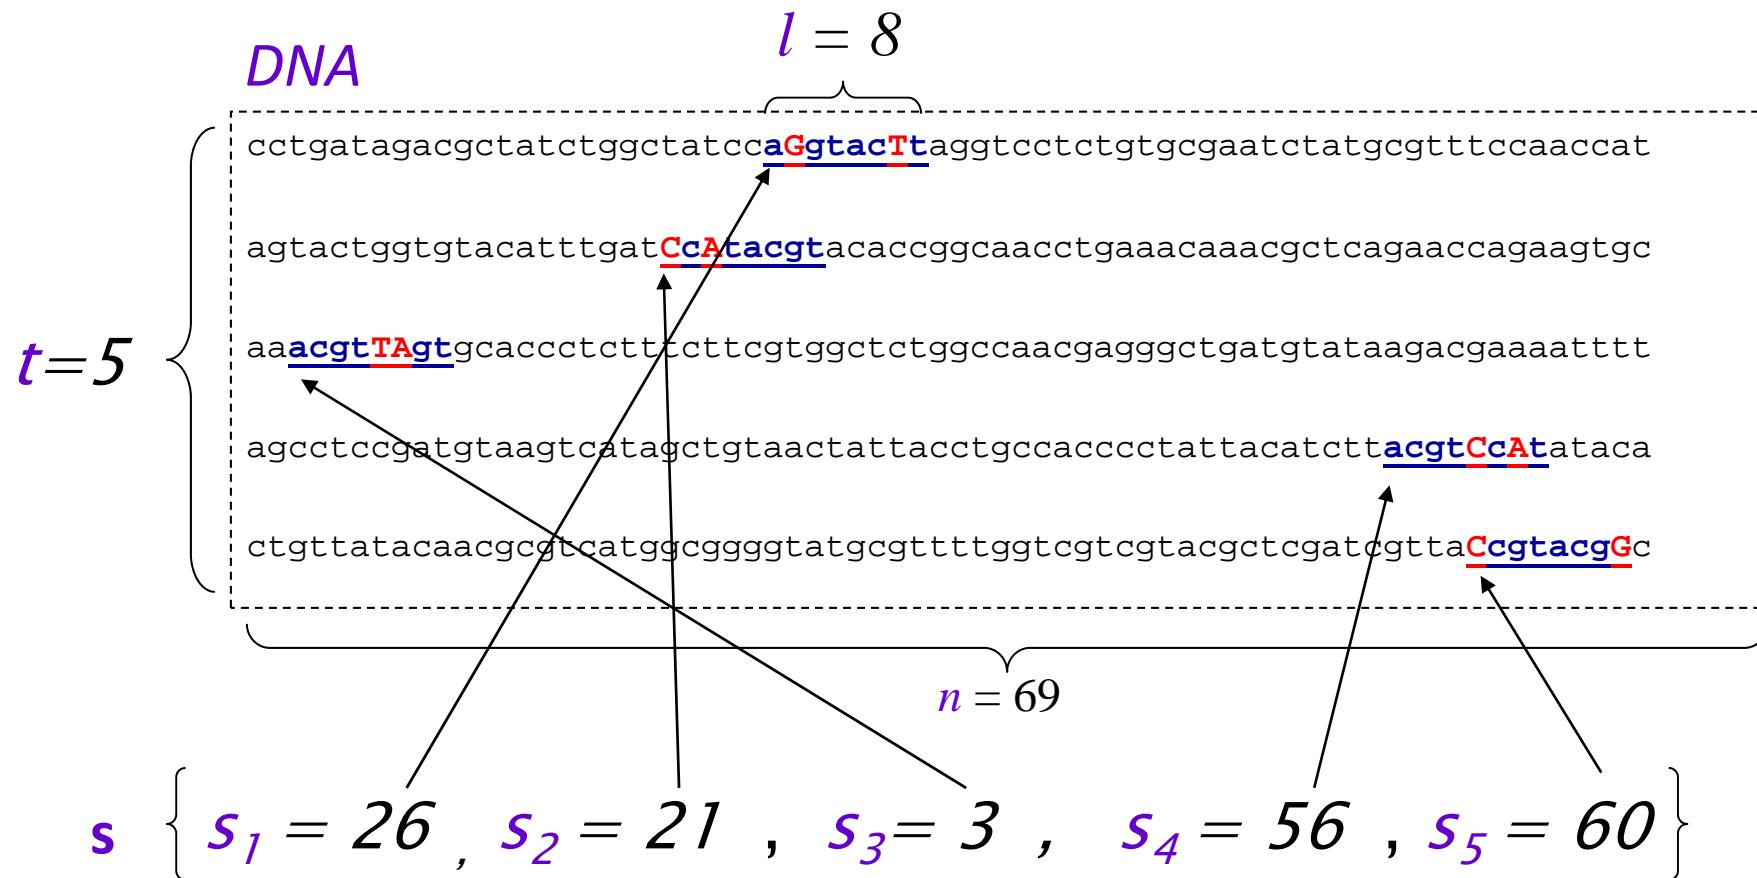

$A(\boldsymbol{\pi})$  - solution produced by algorithm A

$\text{OPT}(\boldsymbol{\pi})$  - optimal solution of the problem

# Performance guarantee

- Performance guarantee of algorithm A is the maximal approximation ratio of all inputs of size  $n$
- For algorithm A that minimizes the objective function (minimization algorithm):
  - $\max_{|\boldsymbol{\pi}| = n} A(\boldsymbol{\pi}) / \text{OPT}(\boldsymbol{\pi})$
- For maximization algorithms
  - $\min_{|\boldsymbol{\pi}| = n} A(\boldsymbol{\pi}) / \text{OPT}(\boldsymbol{\pi})$

# Parameters

# Motifs: Profiles and consensus

Consensus	A C G T A C G T

Score 3+4+4+5+3+4+3+4=30

- Line up the patterns by their start indexes

$$\mathbf{s} = (s_1, s_2, \dots, s_t)$$

- Construct a profile with frequencies of each nucleotide in columns
- Consensus nucleotide in each position has the highest score in column

# Greedy motif finding

- Partial score:  $\text{Score}(s, i, \mathcal{DNA})$ 
  - The consensus score for the first  $i$  sequences
- Algorithm:
  - Find the optimal motif for the two first sequences
  - Scan the remaining sequences only once, and choose the motif with the best contribution to the partial score

# Greedy motif finding

```
GreedyMotifSearch(DNA, t, n, l)
1   s  $\leftarrow$  (1,1, ..., 1)
2   bestMotif  $\leftarrow$  s
3   for s1  $\leftarrow$  1 to n − l + 1
4     for s2  $\leftarrow$  1 to n − l + 1
5       if Score(s, 2, DNA) > Score(bestMotif, 2, DNA)
6         bestMotif1  $\leftarrow$  s1
7         bestMotif2  $\leftarrow$  s2
8     s1  $\leftarrow$  bestMotif1
9     s2  $\leftarrow$  bestMotif2
10    for i  $\leftarrow$  3 to t
11      for si  $\leftarrow$  1 to n − l + 1
12        if Score(s, i, DNA) > Score(bestMotif, i, DNA)
13          bestMotifi  $\leftarrow$  si
14        si  $\leftarrow$  bestMotifi
15    return bestMotif
```

# Running time

- Optimal motif for the two first sequences
  - $l(n - l + 1)^2$  operations
- The remaining  $t-2$  sequence
  - $(t - 2)l(n - l + 1)$  operations
- Running time
  - $O(ln^2 + tl n)$  or  $O(ln^2)$  if  $n \gg t$
- Vastly better than
  - BruteForceMotifSearch:  $(n - l + 1)^t$
  - BruteForceMedianStringSearch:  $4^l$

# Dynamic programming: Sequence alignment

## DNA sequence comparison: First success story

- In 1984 Russell Doolittle and colleagues found similarities between a cancer-causing gene and a normal growth factor (PDGF) gene using a database search
- Finding sequence similarities with genes of known function is a common approach to infer the function of a newly sequenced gene

# Longest common subsequence (LCS) – alignment without mismatches

	<i>i</i> coords:	0	0	1	2	3	4	5	5	6	6	7
elements of <i>v</i>		–	T	G	C	A	T	–	A	–	C	
elements of <i>w</i>		A	T	–	C	–	T	G	A	T	C	
	<i>j</i> coords:	0	1	2	2	3	3	3	4	5	6	7

Matches shown in red

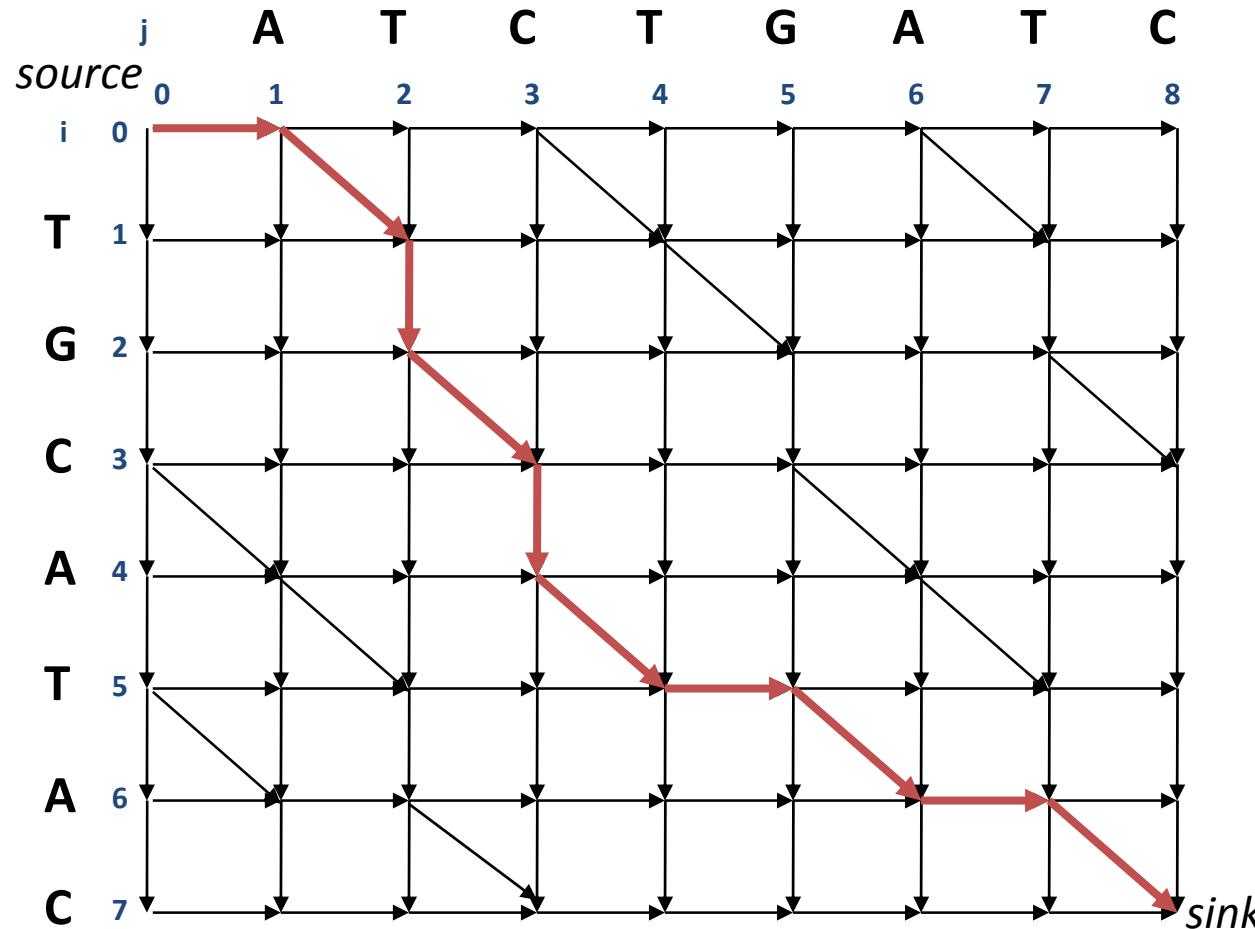

positions in *v* :      1 < 3 < 5 < 6 < 7

positions in *w* :      2 < 3 < 4 < 6 < 8

TCTAC is a common subsequence of *v* and *w*

Every common subsequence is a path in a 2-D grid

# Edit graph for the longest common substring (LCS) problem

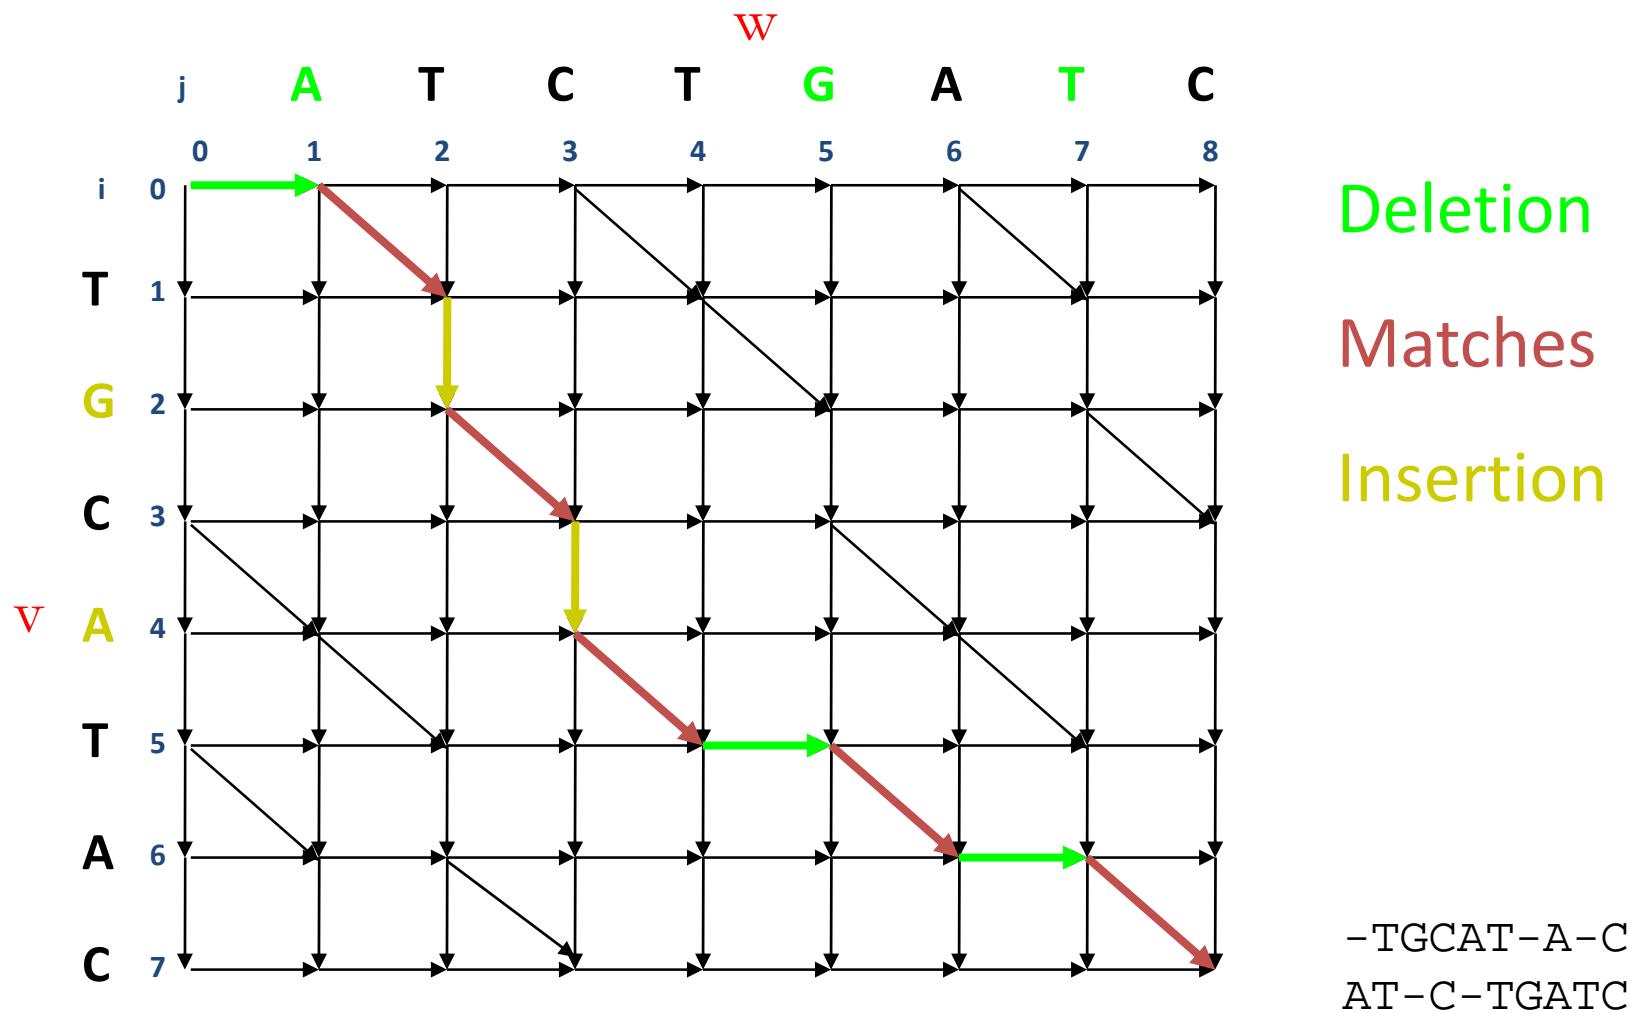

Every path from source to sink is a common subsequence (CS)

Every diagonal edge adds an extra element to the CS

**LCS Problem:** Find the path with the maximum number of diagonal edges

# Edit graph for the LCS problem

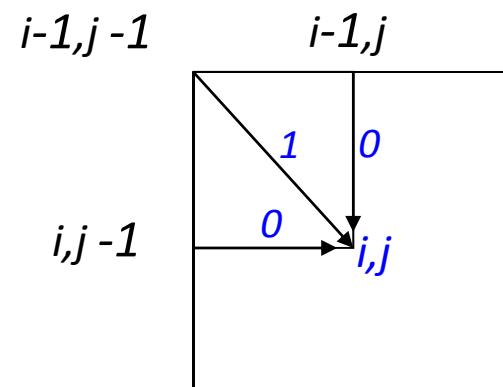

# Computing LCS (I)

Let  $v_i = v_1 \dots v_i$  (prefix of  $v$  of length  $i$ )

and  $w_j = w_1 \dots w_j$  (prefix of  $w$  of length  $j$ )

The length of  $\text{LCS}(v_i, w_j)$  is equal to:

$$s_{i,j} = \max \begin{cases} s_{i-1,j} & \text{Insertion} \\ s_{i,j-1} & \text{Deletion} \\ s_{i-1,j-1} + 1 & \text{if } v_i = w_j \quad \text{Match} \end{cases}$$

# LCS algorithm

$\text{LCS}(v, n, w, m)$

1   **for**  $i \leftarrow 1$  **to**  $n$

2        $s_{i, 0} \leftarrow 0$

3   **for**  $j \leftarrow 1$  **to**  $m$

4        $s_{0, j} \leftarrow 0$

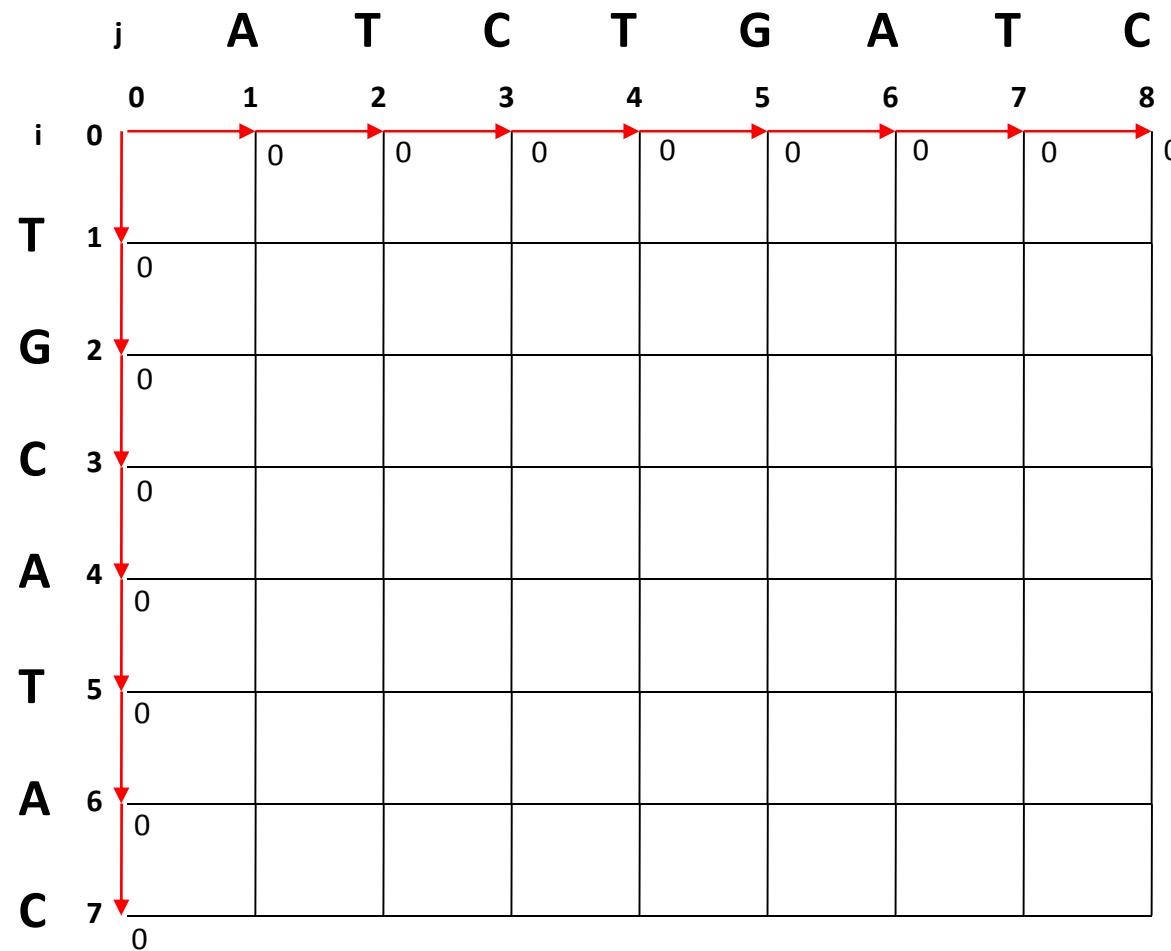

5   **for**  $i \leftarrow 1$  **to**  $n$

6       **for**  $j \leftarrow 1$  **to**  $m$

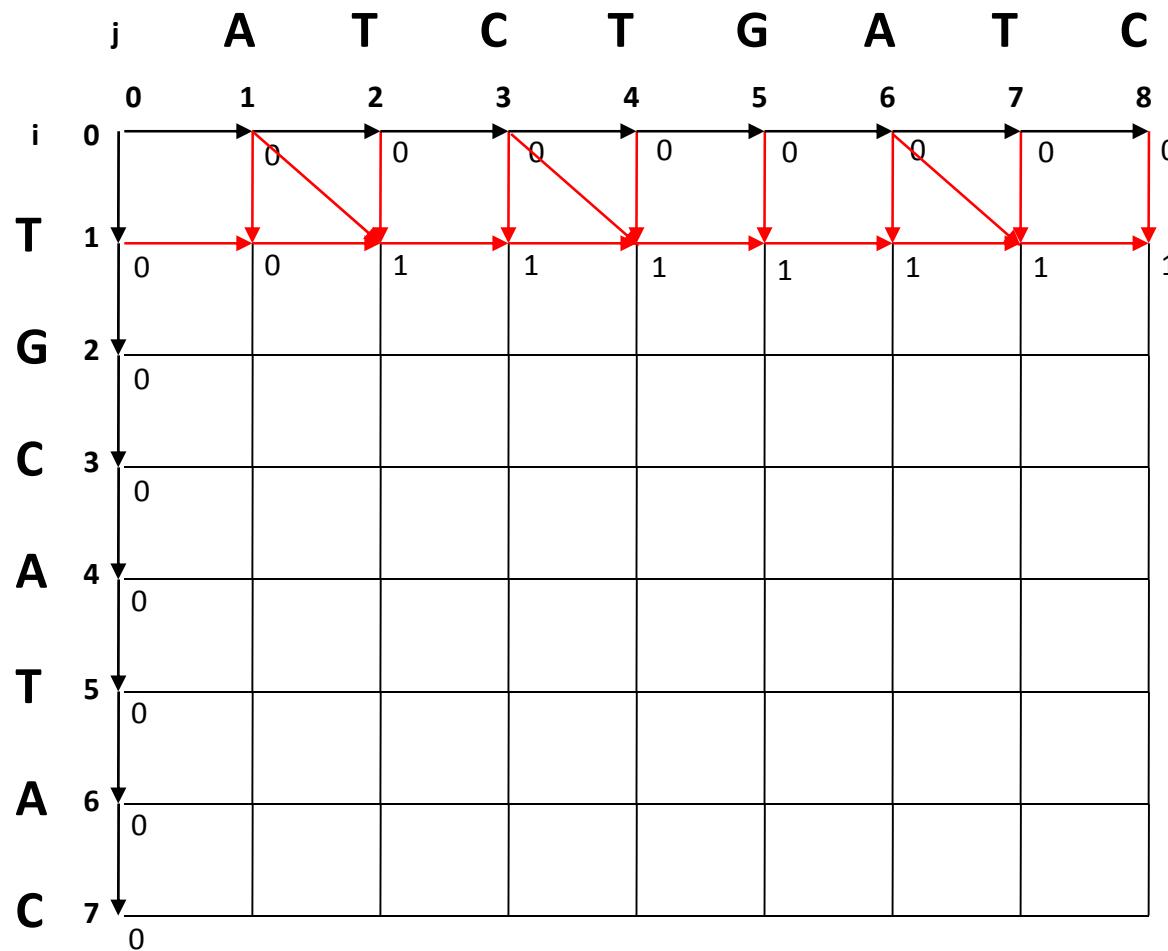

8            $s_{i, j} \leftarrow \max \begin{cases} s_{i-1, j} \\ s_{i, j-1} \\ s_{i-1, j-1} + 1, \text{ if } v_i = w_j \end{cases}$

10   **return**  $s_{n, m}$

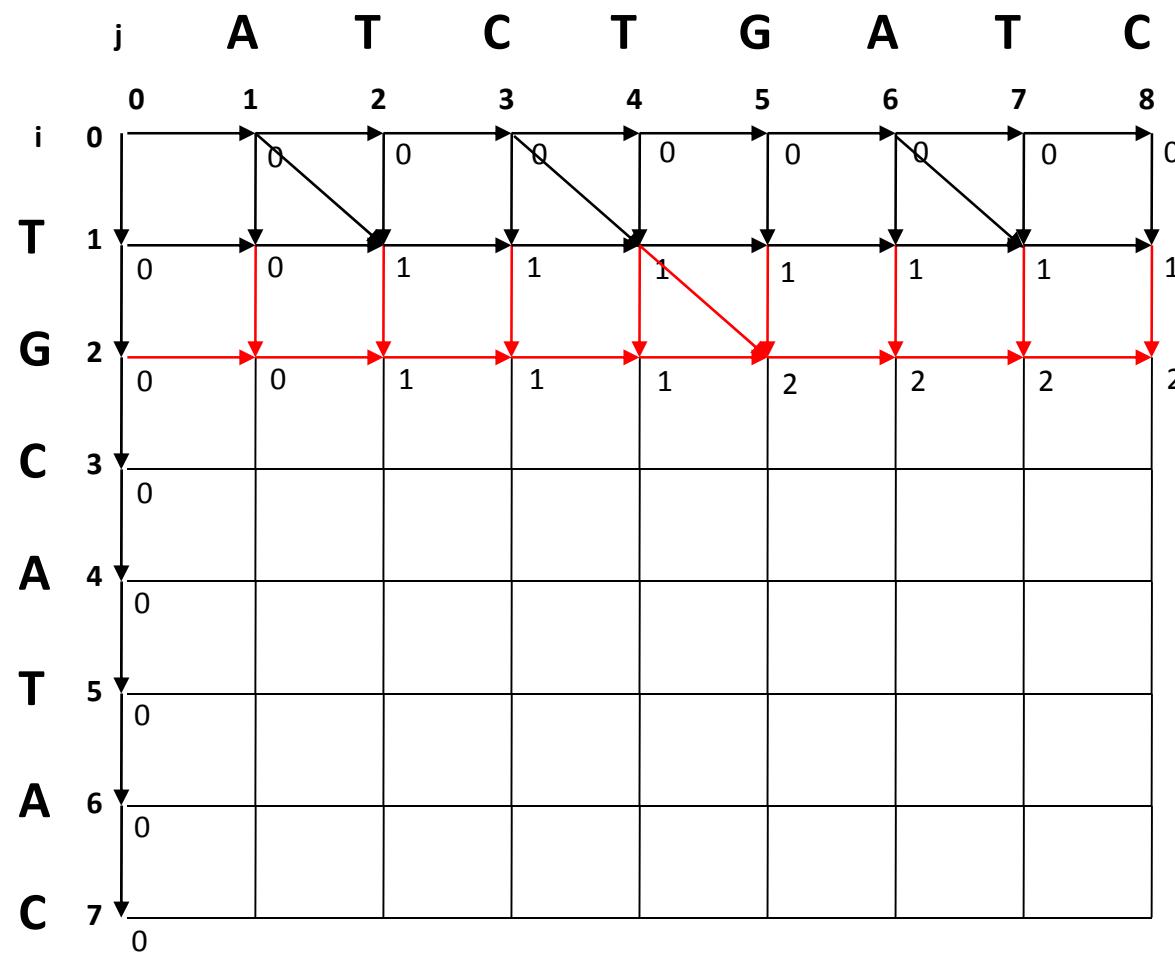

# Example: initiation

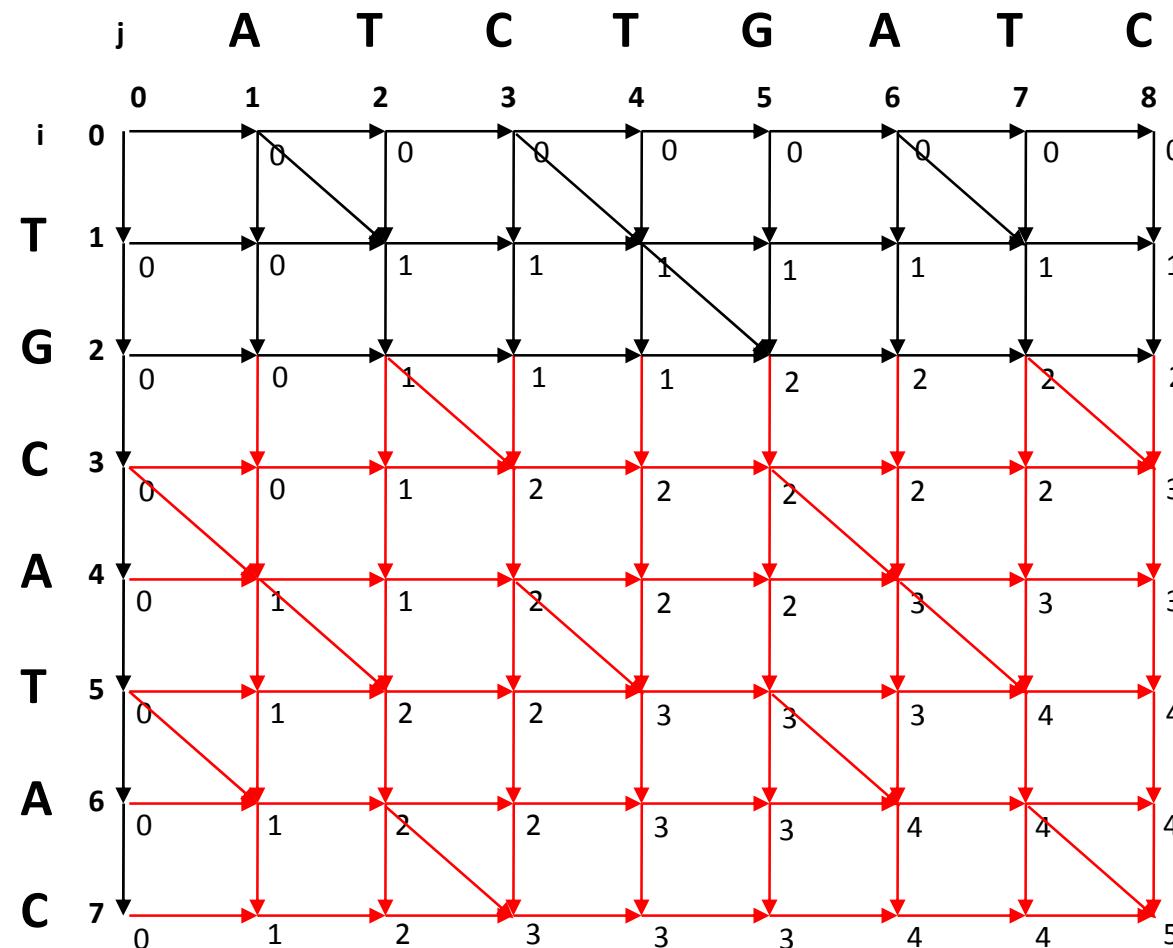

Example: For  $i = 1, j = 1 \dots m$

Example: For  $i = 2, j = 1 \dots m$

Example: For  $i = 3 \dots n, j = 1 \dots m$

# LCS Runtime

- It takes  $O(nm)$  time to fill in the  $n \times m$  dynamic programming matrix
- The pseudocode consists of a nested “**for**” loop inside of another “**for**” loop to set up a  $n \times m$  matrix

# What's so great about dynamic programming?

- A naive exhaustive search would have the running time  $O(3^{f(n,m)})$
- An exhaustive search would recompute the same subpaths several times
- Dynamic programming takes advantage of the rich computational structure in the search space, and reuse already computed subpaths

# Scoring matrix: Example

	A	R	N	K
A	5	-2	-1	-1
R	-	7	-1	3
N	-	-	7	0
K	-	-	-	6

- Notice that although **R** and **K** are different amino acids, they have a positive score
- Why? They are both positively charged amino acids and will not greatly change the function of protein

# Scoring matrices and the global alignment problem

- To generalize scoring, consider a  $(4+1) \times (4+1)$  scoring matrix  $\delta$
- In the case of an amino acid sequence alignment, the scoring matrix would be  $(20+1) \times (20+1)$
- The addition of 1 is to include the score for comparison of a gap character “-” (indels)

$$s_{i,j} = \max \left\{ \begin{array}{l} s_{i-1,j} + \delta(v_i, -) \\ s_{i,j-1} + \delta(-, w_j) \\ s_{i-1,j-1} + \delta(v_i, w_j) \end{array} \right.$$

# Local vs. global alignment (I)

- The **Global alignment problem** : find the longest path between vertices  $(0,0)$  and  $(n,m)$  in the edit graph
- The **Local alignment problem** tries to find the longest path between **arbitrary vertices**  $(i, j)$  and  $(i', j')$  in the edit graph

# Local vs. global alignment (II)

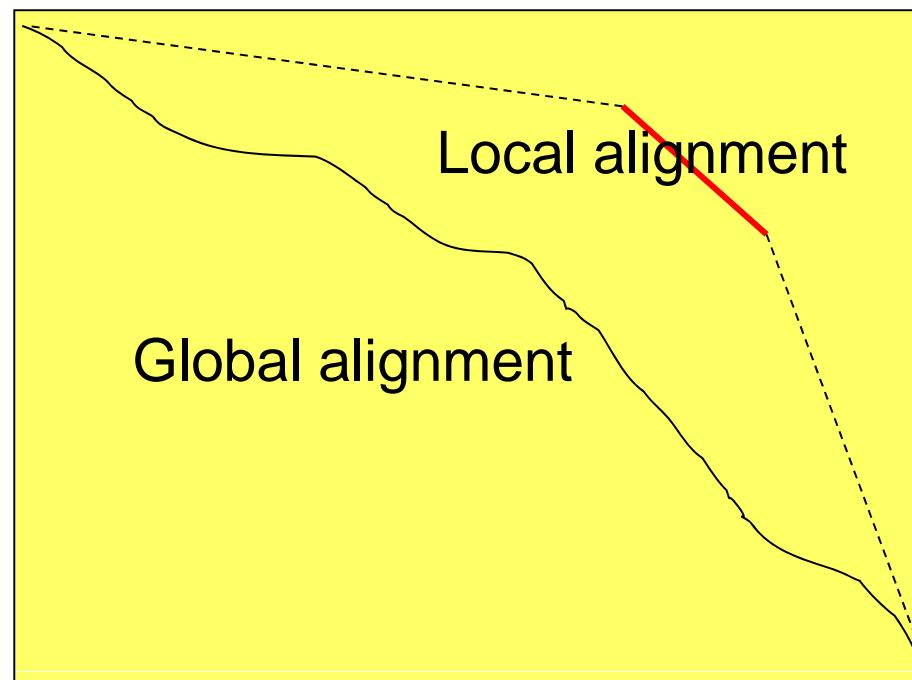

- Global Alignment

```
--T--CC-C-AGT--TATGT-CAGGGGACACG-A-GCATGCAGA-GAC  
| | | | | | | | | | | | | | | | | | | | | | | | | | | | |  
AATTGCCGCC-GTCGT-T-TTCAG----CA-GTTATG-T-CAGAT--C
```

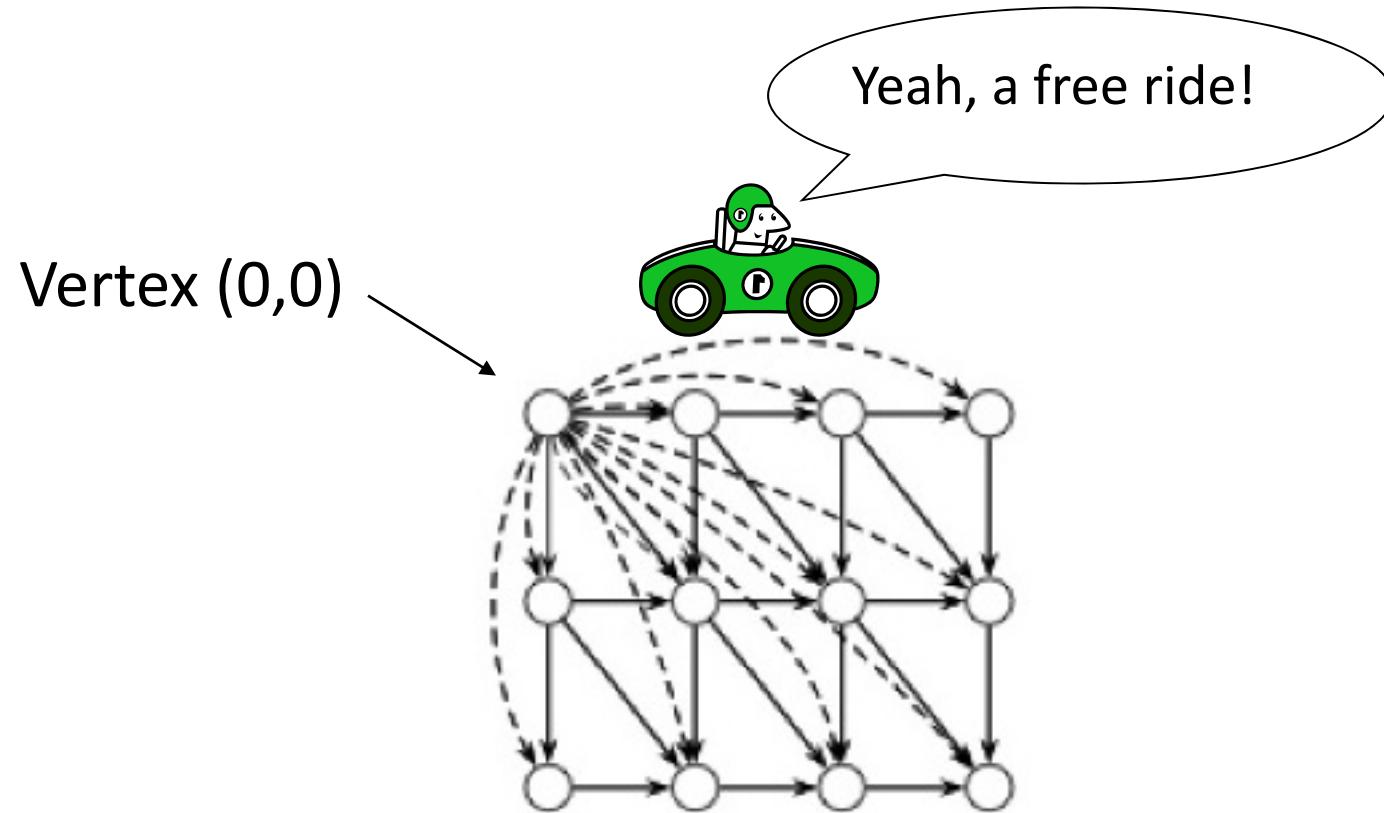

- Local Alignment—better alignment to find conserved segment

```
tccCAGTTATGTCAGggacacgagcatgcagagac  
|||||||  
aattgccgcgtcgtttcagCAGTTATGTCAGatc
```

# Local vs. global alignment (III)

# Free rides

The dashed edges represent the free rides from (0,0) to every other node.

# The local alignment recurrence

- The largest value of  $s_{i,j}$  over the whole edit graph is the score of the best local alignment

$$s_{i,j} = \max \begin{cases} 0 \\ s_{i-1,j} + \delta(v_i, -) \\ s_{i,j-1} + \delta(-, w_j) \\ s_{i-1,j-1} + \delta(v_i, w_j) \end{cases}$$

- The 0 is the only difference from the recurrence of the global alignment problem

# Gap penalties

In nature, a series of  $k$  indels often come as a single event rather than a series of  $k$  single nucleotide events:

ATA--GC

ATATTGC

ATAG- GC

AT- GTGC

This is more likely

Normal scoring would  
give the same score for  
both alignments

This is less likely

# BLAST (I)

- Basic Local Alignment Search Tool (BLAST) finds regions of local similarity between sequences
- The program compares nucleotide or protein sequences to sequence databases and calculates the statistical significance of matches

## BLAST (II)

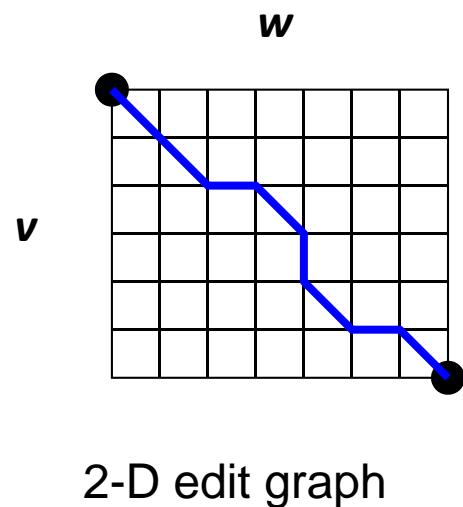

- **First stage:** Identify exact matches of length W (default W=3 ) between the query and the sequences in the database
- **Second stage:** Extend the match in both directions in an attempt to boost the alignment score (insertions and deletions are not considered)
- **Third stage:** If a high-scoring ungapped alignment is found: Perform a gapped local alignment using dynamic programming

# Multiple alignment

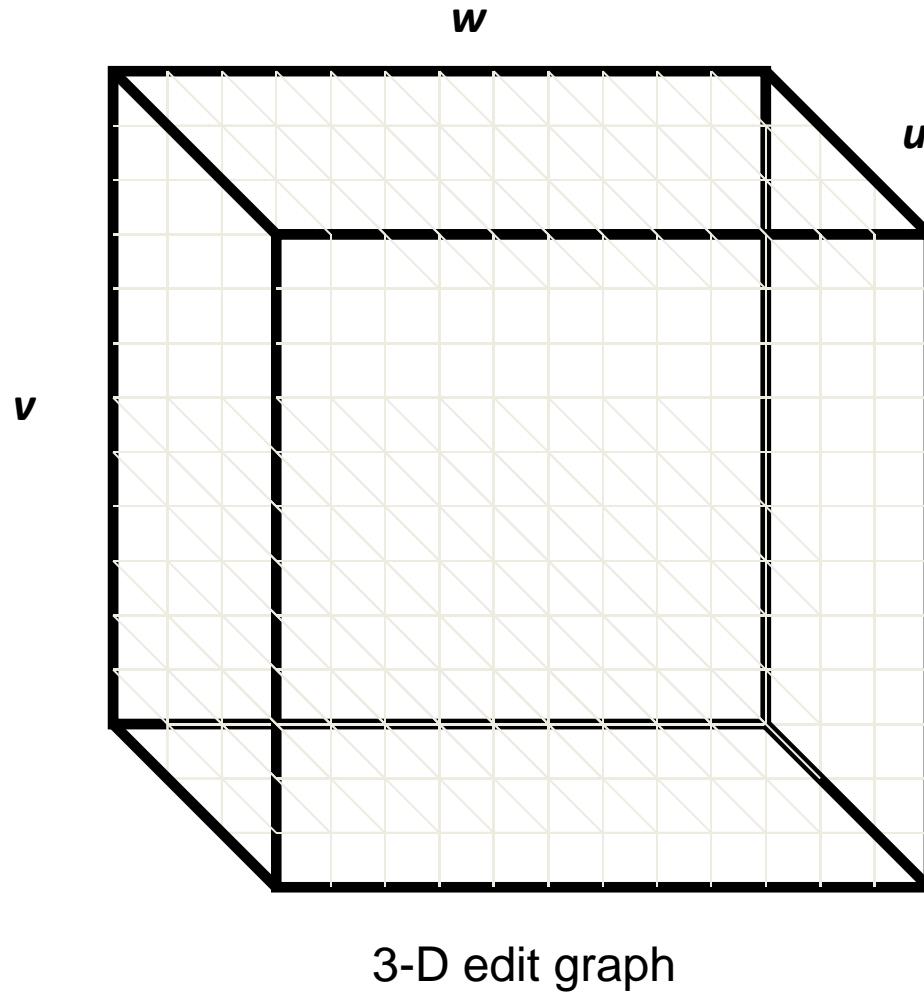

- A faint similarity between two sequences becomes significant if present in many
- Multiple alignments can reveal subtle similarities that pairwise alignments do not reveal

A	T	-	G	C	G	-
A	-	C	G	T	-	A
A	T	C	A	C	-	A

# 2D vs 3D edit graph

2-D edit graph

3-D edit graph

# Multiple alignment: Running time

- For two sequences of length  $n$ , the run time is  $O(n^2)$
- For three sequences of length  $n$ , the run time is  $O(n^3)$
- ...
- For  $k$  sequences, build a  $k$ -dimensional edit graph, with run time  $O(n^k)$
- Conclusion: dynamic programming approach for alignment between two sequences is easily extended to  $k$  sequences, but it is **impractical due to exponential running time**

# Multiple alignment induces pairwise alignments

Every multiple alignment:

**x:** AC-GCGG-C  
**y:** AC-GC-GAG  
**z:** GCCGC-GAG

induces pairwise alignment:

<b>x:</b> ACGCGG-C	<b>x:</b> AC-GCGG-C	<b>y:</b> AC-GCGAG
<b>y:</b> ACGC-GAC	<b>z:</b> GCCGC-GAG	<b>z:</b> GCCGCGAG

# Reverse problem: Constructing multiple alignment from pairwise alignments

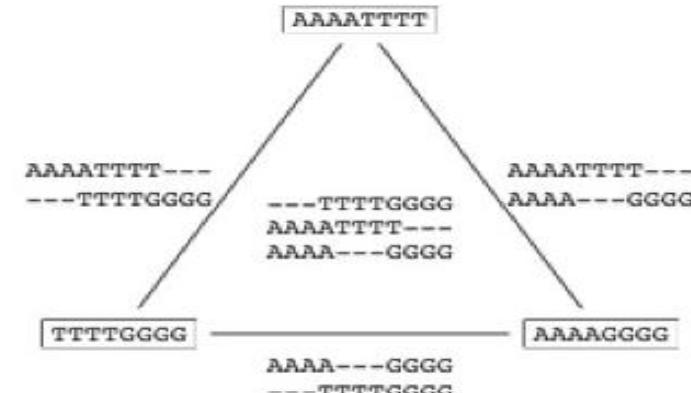

Given three pairwise alignments:

<b>x:</b> ACGCTGG-C	<b>x:</b> AC-GCTGG-C	<b>y:</b> AC-GC-GAG
<b>y:</b> ACGC--GAC	<b>z:</b> GCCGCA-GAG	<b>z:</b> GCCGCAGAG

can we construct the multiple alignment that induces them?

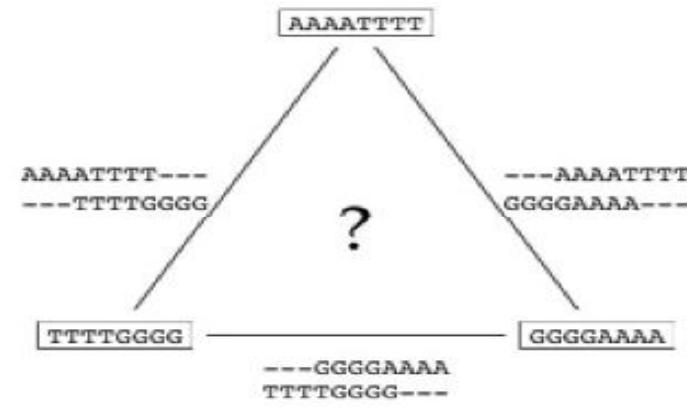

# Combining optimal pairwise alignments into multiple alignment

Can combine pairwise  
alignments into multiple  
alignment

(a) Compatible pairwise alignments

Can not combine pairwise  
alignments into multiple  
alignment

(b) Incompatible pairwise alignments

# Profile representation of multiple alignment

PSSM: Position  
Specific Scoring  
Matrix

- In the past we were aligning a sequence against a sequence
- With profiles we can align a sequence against a profile and even a profile against a profile

# Multiple alignment: Greedy approach

- Choose most similar pair of strings and combine into a profile, thereby reducing the alignment of  $k$  sequences to an alignment of  $k-1$  sequences/profiles. **Repeat!**
- This is a heuristic greedy method

# CLUSTALW

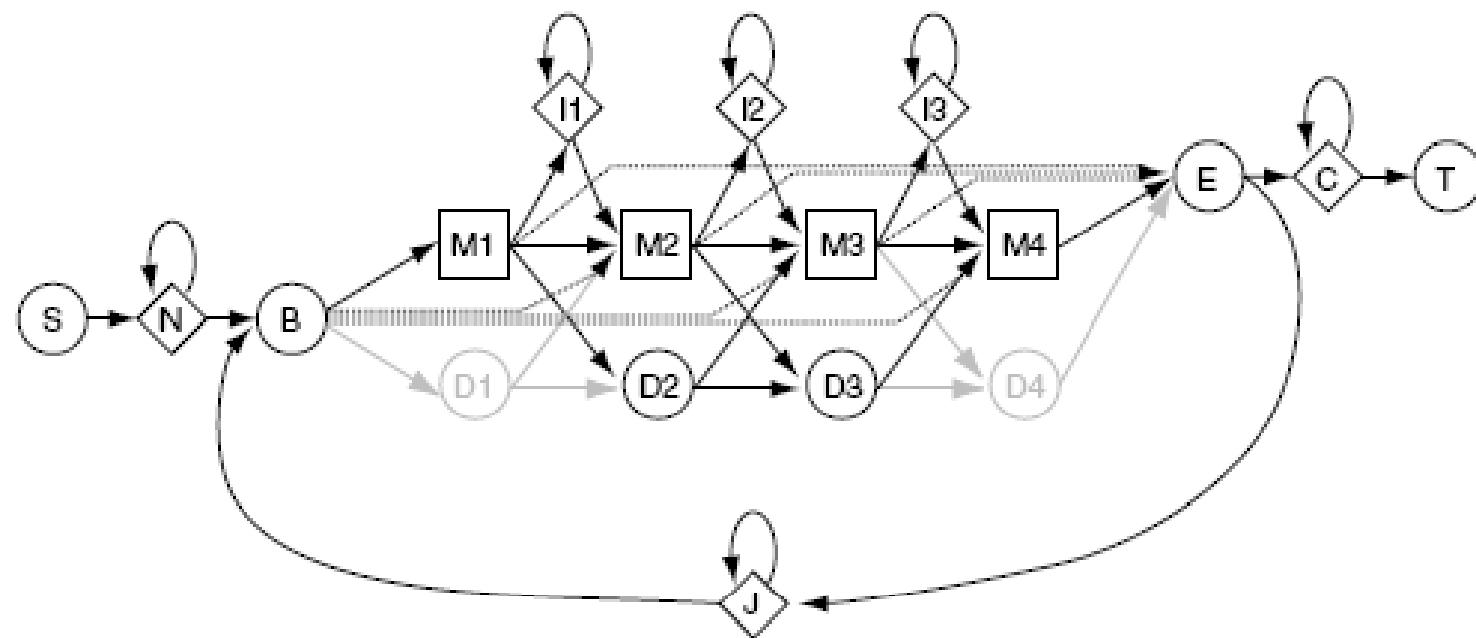

1. Determine all **pairwise alignments** between sequences and the degree of similarity between them.
2. Construct a **similarity tree**.
3. **Combine the alignments** from 1 in the order specified in 2 using the rule "once a gap always a gap".

# PSI-BLAST

- Position-Specific Iterative (PSI) BLAST detect weak relationships between the query and sequences in the database (**higher sensitivity** than BLAST)
- PSI-BLAST first constructs a multiple alignment from the highest scoring hits in a initial BLAST search and generate a **profile** from this alignment i.e. PSSM
- The profile is used to iteratively perform additional BLAST searches (called iterations) and the results of each iteration is used to **refine the profile**
- The iteration stops when no new matches with a satisfactory score are obtained

# Pfam

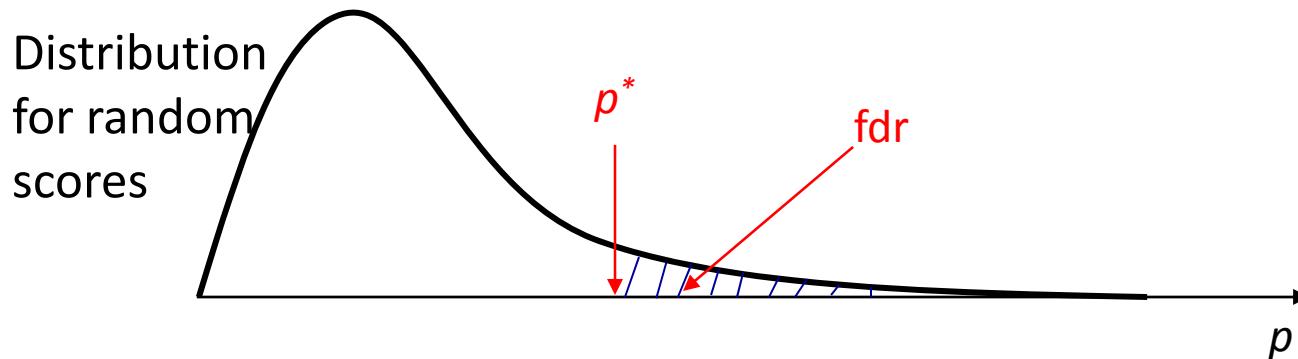

Pfam is a set of protein families (multiple alignments) represented by Hidden Markov Models (HMMs)

# Scoring matches

Given a protein sequence  $\mathbf{x}$  and an BLAST/PSI-BLAST/HMM, what is a significant score?

- The score for the sequence  $\mathbf{x}$ :  $p^*$
- Generate 1000 random sequences and score them:  
 $p_{\text{rand } 1}, p_{\text{rand } 2}, \dots, p_{\text{rand } 1000}$
- Fit a distribution to the random scores and calculate the false discover rate (fdr)
- $E\text{-score} = fdr \cdot \text{Size of query database}$  (the expected number of false positive hits)

# Randomized algorithms

# Randomized algorithms

- Randomized algorithms make random rather than deterministic decisions
- The main advantage is that **no input can reliably produce worst-case results** because the algorithm runs differently each time
- These algorithms are commonly used in situations where no correct polynomial algorithm is known

# Two types of randomized algorithms

- **Las Vegas Algorithms** – always produce the correct solution
- **Monte Carlo Algorithms** – do not always return the correct solution
- Las Vegas Algorithms are always preferred, but they are often hard to come by

# Scoring strings with a profile

Given a profile:  $\mathbf{P} =$

A	1/2	7/8	3/8	0	1/8	0
C	1/8	0	1/2	5/8	3/8	0
T	1/8	1/8	0	0	1/4	7/8
G	1/4	0	1/8	3/8	1/4	1/8

The probability of the consensus string:

$$\text{Prob(aaacct | P)} = 1/2 \times 7/8 \times 3/8 \times 5/8 \times 3/8 \times 7/8 = .033646$$

Probability of a different string:

$$\text{Prob(atacag | P)} = 1/2 \times 1/8 \times 3/8 \times 5/8 \times 1/8 \times 1/8 = .001602$$

## P-most probable $l$ -mer

Define the  $\mathbf{P}$ -most probable  $l$ -mer from a sequence as an  $l$ -mer in that sequence which has the highest probability of being created from the profile  $\mathbf{P}$

$$\mathbf{P} = \begin{array}{|c|c|c|c|c|c|c|}\hline & A & 1/2 & 7/8 & 3/8 & 0 & 1/8 & 0 \\ \hline C & 1/8 & 0 & 1/2 & 5/8 & 3/8 & 0 \\ \hline T & 1/8 & 1/8 & 0 & 0 & 1/4 & 7/8 \\ \hline G & 1/4 & 0 & 1/8 & 3/8 & 1/4 & 1/8 \\ \hline \end{array}$$

Given a sequence = ctataaaccttacatc, find the P-most probable  $l$ -mer

# P-most probable $l$ -mer

P-most probable 6-mer in the sequence is aaacct:

String, Highlighted in Red	Calculations	$Prob(a   P)$
ctataaaccttacat	$1/8 \times 1/8 \times 3/8 \times 0 \times 1/8 \times 0$	0
ctataaaaccttacat	$1/2 \times 7/8 \times 0 \times 0 \times 1/8 \times 0$	0
ctataaaaccttacat	$1/2 \times 1/8 \times 3/8 \times 0 \times 1/8 \times 0$	0
ctataaaacccttacat	$1/8 \times 7/8 \times 3/8 \times 0 \times 3/8 \times 0$	0
<b>ctataaaaccttacat</b>	<b><math>1/2 \times 7/8 \times 3/8 \times 5/8 \times 3/8 \times 7/8</math></b>	<b>.0336</b>
ctataaaccttacat	$1/2 \times 7/8 \times 1/2 \times 5/8 \times 1/4 \times 7/8$	.0299
ctataaaaccttaacat	$1/2 \times 0 \times 1/2 \times 0 \times 1/4 \times 0$	0
ctataaaaaccttacat	$1/8 \times 0 \times 0 \times 0 \times 0 \times 1/8 \times 0$	0
ctataaaacccttacat	$1/8 \times 1/8 \times 0 \times 0 \times 3/8 \times 0$	0
ctataaaacccttacat	$1/8 \times 1/8 \times 3/8 \times 5/8 \times 1/8 \times 7/8$	.0004

# How Gibbs sampling works

- 1) Randomly choose starting positions  
 $\mathbf{s} = (s_1, \dots, s_t)$  and form the set of  $l$ -mers associated with these starting positions
- 2) Randomly choose one of the  $t$  sequences
- 3) Create a profile  $\mathbf{P}$  from the other  $t - 1$  sequences
- 4) For each position in the removed sequence, calculate the probability that the  $l$ -mer starting at that position was generated by  $\mathbf{P}$
- 5) Choose a new starting position for the removed sequence at random based on the probabilities calculated in step 4
- 6) Repeat steps 2-5 until there is no improvement

# Gibbs sampling: an example

## Input:

$t = 5$  sequences, motif length  $l = 8$

1. GTAAACAATATTATAGC
2. AAAATTACCTCGCAAGG
3. CCGTACTGTCAAGCGTGG
4. TGAGTAAACGACGTCCA
5. TACTAACACCCTGTCAA

# Gibbs sampling: an example

- 1) Randomly choose starting positions,  
 $\mathbf{s} = (s_1, s_2, s_3, s_4, s_5)$  in the 5 sequences:

$s_1=7$       GTAAAC**AATATTTA**TAGC

$s_2=11$       AAAATTAC**CTTAGAAGG**

$s_3=9$       CCGTACTG**TCAAGCGT**GG

$s_4=4$       TGAG**TAAACGACGT**CCC

$s_5=1$       **TACTAAC**ACCCTGTCAA

# Gibbs sampling: an example

2) Choose one of the sequences at random:

**Sequence 2:** AAAATTACCTTAGAAGG

$s_1 = 7$       GTAAAC**AATATT**TAGC

$s_2 = 11$       AAAATTAC**C**TTAGAAGG

$s_3 = 9$       CCGTACT**G**TCAAGCGTGG

$s_4 = 4$       TGAG**TAAACG**ACGTCCCA

$s_5 = 1$       **TACTAACACC**GTCAA

# Gibbs sampling: an example

3) Create profile  $\mathbf{P}$  from  $l$ -mers in the remaining 4 sequences:

1	A	A	T	A	T	T	T	A
3	T	C	A	A	G	C	G	T
4	G	T	A	A	A	C	G	A
5	T	A	C	T	T	A	A	C
A	1/4	2/4	2/4	3/4	1/4	1/4	1/4	2/4
C	0	1/4	1/4	0	0	2/4	0	1/4
T	2/4	1/4	1/4	1/4	2/4	1/4	1/4	1/4
G	1/4	0	0	0	1/4	0	3/4	0
Consensus String	T	A	A	A	T	C	G	A

# Gibbs Sampling: an Example

- 4) Calculate the  $\text{prob}(\mathbf{a} \mid \mathbf{P})$  for every possible 8-mer in the removed sequence:

Strings Highlighted in Red	$\text{prob}(\mathbf{a} \mid \mathbf{P})$
AAAATTTACCTTAGAAGG	.000732
AAAATTTACCTTAGAAGG	.000122
AA <del>A</del> ATTTACCTTAGAAGG	0
AAA <del>T</del> TTTACCTTAGAAGG	0
AAAAT <del>T</del> TACCTTAGAAGG	0
AAAAT <del>T</del> TACCTTA <del>G</del> AAGG	0
AAAATT <del>T</del> ACCTTAGAAGG	0
AAAATT <del>T</del> ACCTTAGAAGG	.000183
AAAATTTACCTTAGAAGG	0
AAAATTTAC <del>C</del> TTAGAAGG	0
AAAATTTACCTTAGAAGG	0

# Gibbs Sampling: an Example

- 5) Create a distribution of probabilities of  $l$ -mers  $\text{prob}(\mathbf{a} | \mathbf{P})$ , and randomly select a new starting position based on this distribution

To create a proper distribution, divide each probability  $\text{prob}(\mathbf{a} | \mathbf{P})$  by the sum of probabilities over all position:

Probability (Selecting Starting Position 1) = 0.706

Probability (Selecting Starting Position 2) = 0.118

...

Probability (Selecting Starting Position 8) = 0.176

# Gibbs sampling: an example

Assume we select the substring with the highest probability – then we are left with the following new substrings and starting positions

$$s_1=7$$

GTAAAC**AATATT**TAGC

$$s_2=1$$

**AAAATT**A CCTCGCAAGG

$$s_3=9$$

CCGTACTG**TCAAGCGT**GG

$$s_4=5$$

TGAG**TAATCGA**CGTCCC

$$s_5=1$$

**TACTCAC**ACCCTGTCAA

# Gibbs sampling: an example

- 6) We iterate the procedure again with the above starting positions until we cannot improve the score any more

# Gibbs sampler in practice

- Gibbs sampling needs to be modified when applied to samples with unequal distributions of nucleotides (*relative entropy* approach)
- Gibbs sampling often converges to locally optimal motifs rather than globally optimal motifs
- Needs to be run with many randomly chosen seeds to achieve good results
